
Social Security Administration

WORKING PAPER

*Developing an
Initial Classification System*

June, 2009

This working paper was prepared by staff of the Social Security Administration's Office of Program Development and Research in the Office of Retirement and Disability Policy for the Occupational Information Development Advisory Panel.

Developing an Initial Classification System

This document describes SSA's proposed plans for developing a classification system, or *taxonomy*, of occupations for use in the Occupational Information System (OIS) being developed to replace the *Dictionary of Occupational Titles* (DOT). We intend for the paper to serve as a starting point for Occupational Information Develop Advisory Panel discussion and deliberation. We will use the Panel's recommendations to develop our final plans and methods for developing an initial classification. In the sections below, we begin by summarizing the various types of taxonomies that we think are needed for the new OIS, and the characteristics that a sound taxonomic structure should possess.

We then describe the two-phase process that SSA will use to develop a new title taxonomy, which will begin by constructing an initial taxonomy that will be used during the initial population of the OIS database. After the database is sufficiently populated using our job-side data collection survey, a revised title taxonomy will be developed. As the OIS database grows over time, periodic updates to the taxonomic structure will be developed.

Before we get into the specifics of developing a classification system, we should pause and recall what SSA's actual requirements are for an OIS and why this process is such a challenge. Briefly, any occupational resource that SSA uses must meet at least three criteria. First of all, the OIS needs to reflect the national existence and incidence of work. The OIS must even include jobs that are only available in certain regions of the country. Secondly, the OIS must reflect work requirements at such a level of aggregation that it enables SSA to compare the work requirements of occupations with an individual's ability to perform work. Thirdly, the OIS must be legally defensible. SSA must meet a burden of proof regarding a determination that a claimant has the ability to perform other work in the national economy. Although the DOT is imperfect, its level of occupational title taxonomy is not overly abstract, and it has withstood challenges in court. In short, the level of aggregation of occupations must be granular enough to capture information specific to an occupation to allow for disability evaluation but high enough to be manageable in terms of measurement, data collection, and the utility of the occupational classification system. The OIS must reflect occupations that are aggregated so that they are as homogeneous as possible for elements that are most critical to SSA. Determining this level of aggregation presents perhaps one of the biggest challenges for the new OIS.

Role of Taxonomies in the OIS

Job- and Person-side taxonomies. Several different types of taxonomic structures will be used in the new OIS. Figure 1 summarizes the two taxonomies that are most relevant to the *content model* that will be implemented in the new OIS. These taxonomies tell us what *kind of information* we should collect to describe work activities and characteristics (the *job side* of Figure 1) versus the personal attributes of workers or claimants (the *person side* of Figure 1).

A common characteristic of taxonomies is that they tend to exhibit a hierarchical structure, ranging from high detail at the lower end to high abstraction at the upper end. The various degree-of-specificity levels of the taxonomy are denoted by the Level 1 through Level 5 labels on the right.

Occupational title taxonomy. Although the above two taxonomies of work-content and worker-characteristics are critically important in the new OIS, they are not the focus of this paper. Rather, the taxonomy that is of interest here concerns the way in which *occupational titles* are identified and described.

Simply put, the two taxonomic structures illustrated in Figure 1 tell us *how to describe* the aspects of the world of work that are relevant to disability determination. The occupational title taxonomy, in contrast, tells us *what organizational entities* should be described in the new OIS. In the DOT, the rated entities were *occupations*, and we intend to continue to use that level of analysis in the new OIS as well.

Figure 2 illustrates the hierarchical nature of title taxonomies. The lower end of Figure 2 provides the most specificity, describing individual *positions* in the economy. Here, a position is defined as the tasks, duties, and responsibilities that are assigned to a single worker; unless there are unfilled positions, the number of positions equals the number of employees in an organization.

In a very important sense, the position represents the only “real” or non-hypothetical aspect of the title taxonomy. That is, positions clearly exist, and the work that is performed by the position *incumbent* can be objectively observed and described. In contrast, all of the higher-level entities in Figure 2 are to varying degrees *hypothetical constructs* that we use to simplify the task of describing work.

The *job* defines the level of abstraction above the position (denoted Level 2); as Figure 2 illustrates, jobs are formed by combining similar positions within a given organization. Given that the different people who perform a job often perform it somewhat differently, or perform it in different situations or locations, the job represents an *abstraction* or hypothetical entity. The key characteristic that must be satisfied when clustering positions to form jobs is that the work performed (and worker requirements) across the positions in question must be *similar enough that they can share the same job description and selection standards*.

Although some degree of within-title variability is typically seen between the work activities performed by the various positions in a given job, it must not be so large that a single job description cannot accurately describe all of the positions in the title. Likewise, cross-position variability cannot exist to the point that different *levels* or *types* of worker-requirement characteristics (abilities, skills, experience, knowledge) are required to perform the different positions in a job. In such cases, a single job description or set of selection standards is not sufficient, and the title should be split into more homogeneous clusters.

The horizontal dashed line in Figure 2 separates entities that exist *within* individual organizations or companies (below the line) versus entities that exist *across* organizations. The *occupation* defines the next level of abstraction (i.e., Level 3) in Figure 2; occupations are defined as collections of jobs that exist across a number of organizations, and that are similar enough with respect to their work activities and worker requirements that they can be treated interchangeably *for some purpose*. The term *job family* is at times used synonymously with occupation.

It is important to stress the purpose-specific nature of the above definition. That is, collections of jobs may be similar enough to share an occupational or job-family title for some applied purposes (e.g., to set employee-selection standards using general cognitive or physical ability tests), but not similar enough to be viewed as interchangeable for others (e.g., developing a training program).

In our context, the purposes that concern SSA when forming an occupational taxonomy center on the various decisions that must be made during the disability determination process. Although to some degree these purposes may appear to be similar to those involved in employee selection and/or placement applications, they may also diverge in important respects. In particular, for many of the uses to which this information will be put, SSA arguably requires more finely-delineated occupations for disability-determination than might be needed for other purposes (e.g., setting compensation rates, determining whether a general ability test is a valid predictor of job performance). This is due to the fact that for SSA's purposes, the occupational groupings must be sufficiently homogeneous with respect to all of the work activity and/or worker-requirement attributes that are relevant to the disability adjudication issue at hand.

Because the number of these attributes could potentially be quite large, this implies that the number of occupational titles required to form homogeneous clusters could also be appreciably larger than the number seen in, for example, the SOC taxonomy. However, such a system could still be sufficiently more parsimonious than the DOT taxonomy, as it is possible that many titles that are distinct in the DOT would be found to be sufficiently homogeneous on the disability-related attributes of interest to us to justify being combined into a common title.

As a result of this divergence, the taxonomic structure that SSA determines is optimal for our needs may well differ substantially from the occupational taxonomies that are

deemed adequate for other purposes by other organizations. As was discussed in more detail in the *SSA Concerns Regarding O*NET* (2009) document, this is one of the reasons why SSA determined that the O*NET system, and its underlying Standard Occupational Classification (SOC) title taxonomy, was not suitable for our disability adjudication needs. Instead, we need a level of specificity closer to that seen in the DOT.

The next level up in terms of abstraction (Level 4) in the Figure 2 hierarchy consists of clusters of DOT-level occupations that are deemed similar-enough for some purpose(s) to be able to share a common description of their activities and worker requirements. The *occupational units* (OUs) used by the O*NET and SOC taxonomies provide examples of this level of abstraction.

Although this level of abstraction may be deemed adequate to address some applied functions, SSA has determined that it is too abstract for disability evaluation. That is, because dozens or hundreds of DOT-level occupations are combined to form a single OU in the O*NET/SOC taxonomies, the amount of within-OU variability with respect to both work activity and worker-trait requirements is often substantial. This issue is discussed further in the following section.

Finally, at Level 5 of the hierarchy are the types of job families that many proponents of *validity generalization* (VG) view as representing the correct level of abstraction for identifying worker-selection requirements on general cognitive, physical, and similar tests. Although some authors have argued that only two or three Level 5 clusters are needed for employee selection purposes using a VG-based argument, it would of course be possible to specify a larger number than the three shown in Figure 2 and still define clusters having this highest level of abstraction.

Given that SSA has determined that the degree of abstraction seen in the Level 4 clusters used in O*NET/SOC is too abstract for disability adjudication, these Level 5 clusters are of little interest in our taxonomic work. In the following section, we examine the desirable characteristics of an effective title taxonomy.

Characteristics of a Good Title Taxonomy

Describes all jobs in the economy. Perhaps it appears somewhat obvious, but it bears stating that one essential characteristic of a good title taxonomy for SSA's purposes is that it comprehensively describes all work that exists in the economy, and that it is able to classify every job or occupation in the economy into one of its title clusters. That is, while some sectors of the labor market may be more important to SSA disability adjudication than others, the OIS should reflect all the work in the U.S. economy based on the extent to which the OIS groupings of occupations result in acceptable levels of homogeneity for elements that are most critical to SSA.

Indeed, the O*NET/SOC taxonomy does not classify *one in five* DOT occupations into a functional OU category. Instead, they have been grouped with “all other” titles that are not rated, and for which O*NET does not report occupational information.

Clearly, SSA does not have the luxury of developing a title taxonomy that is so abstract, or constructed in such a non-comprehensive fashion, that DOT-level occupations by the thousands cannot meaningfully be slotted into it (as is the case with the O*NET/SOC taxonomy). Being able to exhaustively define all work as it exists in the economy is essential for any taxonomy used at SSA because we must evaluate claimants’ past work and, at times, we must assess the extent to which claimants’ skill may transfer to other work for which they retain the functional capacity to do.

Consistent level of granularity. Another presumably obvious characteristic that should be possessed by a high-quality title taxonomy is that its occupational clusters should define a consistent level of detail or granularity across the taxonomy. That is, regardless of the total number of titles, it should not be the case that some titles are much more finely defined than others.

For example, although approximately one in eight O*NET/SOC titles contains only one DOT occupation, others contain hundreds (and in one case, almost 1,600) individual DOT occupations. Similarly, an examination of the titles in the SOC taxonomy suggests that it defines work using a highly variable level of granularity. That is, although the O*NET/SOC taxonomy reflects separate titles for *Industrial-Organizational Psychologist*, *School Psychologist*, *Clinical Psychologist*, *Counseling Psychologist*, and *Psychologist/All Other*, it combines over 700 DOT occupations as diverse as *Dispatcher*, *Wrecking Supervisor*, *Uranium Processing Plant Supervisor*, *Head Grease Maker*, *Chief Projectionist*, and *Mexican Food Cook* into a single title called *First Line Supervisors/Managers of Production and Operating Workers*. Also, the O*NET/SOC has separate titles for *Gaming Change Persons and Booth Cashiers* and *Gaming Cage Workers*, but 18 other titles including *Food Checker*, *Toll Collector*, and *Paymaster of Purses* are combined into a single OU labeled *Cashiers*.

Acceptably low within-title heterogeneity. Perhaps the most critical characteristic that a high-quality occupational title taxonomy will exhibit concerns the degree of within-title variability that is present between the jobs that are combined to form Level 3 occupations (or the occupations that are combined to form Level 4 clusters). The bottom-line test of whether this has been done accurately is to ask whether all of the entities that are clustered together to form a title are *similar enough* with respect to the relevant work activities and worker-trait requirements of interest to share a single description of their activities (and set of worker-requirement standards).

To illustrate why heterogeneity poses such a problem for SSA, Figure 3 presents a bubble plot of the numbers of DOT occupations that receive various combinations of ratings on the *Strength* (the vertical axis) and *SVP* (horizontal axis) scales from the DOT for the SOC title of *Carpenters*. Solid circles represent the DOT occupations considered “core”

by the O*NET, and the dashed circles represent ones that would be ignored when computing the OU-mean levels of *Strength* or *SVP* for this title. Figure 4 presents a plot of the factor-score profiles for the DOT occupations that were grouped to form this SOC cluster (each line connects the scores for each DOT title on ten factors that were extracted from the 63 DOT worker-requirement scales).

As an inspection of the results in Figures 3 and 4 readily indicates, a massive level of within-OU variability exists in this SOC title, both with respect to the relatively focused issue of the overall *Strength* and *SVP* requirements (which range from *Unskilled* to *Skilled*, and from *Medium* to *Very Heavy*) as well as the more detailed similarity on the collection of characteristics rated by the DOT. Unfortunately, the level of within-title variability shown in this example is widespread in the O*NET/SOC taxonomy.

In sum, for SSA's purposes, it is essential that we satisfy all of the above criteria. Arguably, the root cause of the fundamental problems seen in the O*NET/SOC title taxonomy can be traced back to the manner in which the occupations were classified. Classification is a critical and formative step in the development of an effective OIS.

Developing an Initial Classification System

Picking a starting point. The process of developing an initial title taxonomy for use in SSA's new OIS presents something of a chicken-and-egg situation. That is, to begin collecting data and populating our OIS, we must know *which* organizational entities (Figure 2) we will be targeting for description. However, until we have a large database in hand that was collected using the items contained in our SSA-optimized content model (the job-side of Figure 1), we will not be able to identify an optimal title taxonomy (particularly, with respect to meeting the third taxonomic goal of adequate within-title homogeneity).

Obviously, we need to start somewhere. The strategy we plan to follow involves developing an *initial* classification taxonomy that we do not anticipate will be retained over the long-term, but that will be adequate for beginning the data collection process and providing a way to transition from the DOT-based taxonomic system now used by SSA.

This initial taxonomy will be informed and refined by job analysis data that SSA is able to gain access to *prior* to developing and using our own data-collection instruments that implement the job-side of the content domain illustrated in Figure 1. Because the DOT is the taxonomic system now used, the initial taxonomy must be constructed in a fashion that links each DOT occupation to the tentative clusters that will be used to guide sampling when data collection is initiated for the new OIS.

Accordingly, unless additional databases can be located that describe the full range of DOT titles on attributes that we find to be relevant to the disability determination process, it is anticipated that we will rely on the most recent versions of RHAJ-type scale ratings produced by the DOT. Although several dozen scales rated by the RHAJ process define a

broad range of work activity and worker-requirement data, to develop the final taxonomy to be used in the new OIS we would prefer to have a higher level of detail (and verifiability) for selected data elements than is possible using the RHAJ scales. Some of the RHAJ scales are appropriate for SSA's purposes.

Information relevant to the prevalence of work in the economy – either in general, or with respect to the occupations that are most prevalent in actual disability claims – will also be considered when developing the initial taxonomy. Table 1 presents a listing of the SOC-level titles and the numbers of employees in each (as of May 2008), as well as information regarding the average level of variability within each SOC title between its DOT occupations.

As an inspection of the information in Table 1 indicates, a small number of SOC titles may capture a large percentage of the workforce (e.g., the top 50 SOCs contain over 50% of all employees). Such information (particularly information on the occupations having the highest numbers of claimants) can be very helpful in prioritizing our initial data collection efforts.

Can't we just use the SOC? Simply put, no. That is, SSA cannot simply use the SOC system directly without linkage or crosswalk. SSA needs an occupational classification system that offers more specificity than one aggregated at the SOC level. Therefore, although it would dramatically simplify matters if SSA could just adopt the SOC or O*NET/SOC title taxonomies as the basis for forming our new OIS, the concerns we identify above in those taxonomies preclude such a course of action.

We will of course be mindful of the need to develop a way to crosswalk the titles contained in the SSA title taxonomy back to the SOC. However, there is no question that the O*NET/SOC level of abstraction is too abstract for SSA to use directly, as an examination of the within-SOC variability indices presented in Table 1 illustrates.

For each SOC cluster, Table 1 reports within-cluster variability measures derived from the average profile difference (measured as a Euclidean distance) between each DOT title in the cluster and the SOC-mean profile. To define each DOT occupation's characteristics, scores on the 10-factor solution produced by Harvey and Wilson (2009) were used. These ten factors were formed by statistically combining ratings of 63 separate DOT work-activity and worker-requirement scales from the RHAJ.

Table 1 expresses the average within-cluster distance for each SOC in two ways: the 'zDist' value is the standardized distance (mean = 0, SD = 1) across all SOC clusters; the 'pctMaxDist' value expresses the average distance as a percentage of the value seen in the SOC title with the highest variability (which occurred for *Actors*, which receives a value of 100). For both indices, numerically larger values indicate higher within-SOC heterogeneity.

For example, the *Cashiers* SOC title contains 18 DOT titles that were rated on the DOT RHAJ scales; the standardized-distance index of 0.17 indicates that it lies slightly above the mean level of within-title heterogeneity seen across all SOC titles. The percent-distance index indicates that the average within-title variability across the DOT titles in the *Cashiers* SOC is 43% of the maximum value seen in the *Actors* title.

Two general points can be made regarding the within-title heterogeneity results in Table 1. First, even within-cluster distance values that lie well below the average may still reflect levels of heterogeneity that are unacceptably high for SSA's purposes. For example, the results in Figures 3-4 for *Carpenters* clearly show that excessive levels of disagreement on both *Strength* and *SVP* exist between the DOT-level titles grouped to form this SOC. However, the average distance in *Carpenters* is only 57% of the level seen in the most-heterogeneous SOC (*Actors*).

Likewise, although all of the example occupations that were examined in the Harvey and Wilson (2009) study were deemed to exhibit excessive levels of within-title variability, some of them scored below the average level of within-SOC variability (e.g., *Sewing Machine Operators*, which lies one-half standard deviation below the mean, and is only 33% of the maximum distance). In light of the fact that only 13 of the top 100 SOC titles by employment show percent-distance values under 30% – and of these, only 4 have at least 5 DOT titles, and only 1 has more than 10 – the Table 1 results indicate that with respect to the work demands measured by the RHAJ scales, the SOC system is too internally heterogeneous for SSA's needs.

Second, the amount of within-SOC disagreement across DOT titles is largely unrelated to the number of DOT titles that were combined to form the SOC title. Although combining hundreds or thousands of DOT titles to form a single SOC title clearly invites problems with respect to within-title heterogeneity, unacceptably high levels can be seen even in clusters with far fewer DOT-level titles. For example, the *Electricians* title has only 14 DOT titles, but a very high level of disagreement; among the 20 SOC titles showing the highest within-title disagreement, 14 contain less than 10 DOT titles. These results highlight the importance of identifying and measuring all of the work-activity and worker-requirement criteria of importance to SSA, and then ensuring that our occupational clusters are relatively homogeneous with respect to these characteristics.

Analytic strategies. In terms of the analytical procedure to be used, SSA will evaluate the performance of a range of multivariate techniques with respect to analyzing the profile similarities between the DOT occupations. For example, factor analytic methods may be used to first reduce the dimensionality of the DOT ratings to a more parsimonious profile (e.g., as was done to compute the factor scores in Figure 4), and follow by using hierarchical clustering methods to identify groupings of relatively homogeneous DOT titles.

The potential for working backward from the existing SOC taxonomy (i.e., by splitting SOC clusters of DOT titles until relatively homogeneous clusters are identified) will also

be examined. Such an approach offers advantages with respect to allowing the development of a crosswalk from the new SSA OIS taxonomic system to the SOC.

Hybrid methods incorporating *genetic algorithm* (GA) methods will also be evaluated. Here, we could combine a brute-force agglomerative clustering approach such as Ward's method (which begins with all DOT-level occupations in separate clusters) with a custom GA that allows consideration to be given to the known constraints that exist (i.e., the ways in which the DOT-to-SOC crosswalk links these two taxonomic domains). This type of hybrid approach could allow us to avoid being limited by mistaken linkages in the current DOT-to-SOC crosswalk, while still being able to be highly sensitive to the need to form relatively homogeneous clusters of DOT titles.

In sum, with respect to developing our initial taxonomy for the new OIS, there is no one single “true” cluster solution for clustering DOT titles that is optimal for SSA. This is particularly the case due to the fact that we are limited to using existing data to describe each DOT occupation. In the final analysis, SSA will evaluate a range of methods, and in conjunction with the Advisory Panel, evaluate a number of possible solutions to determine which will be chosen for actual use.

Role of Advisory Panel. SSA will rely on the Advisory Panel’s recommendations to inform its development of an initial classification taxonomy of occupations. These recommendations should be premised on the fact that the process of developing SSA’s initial classification taxonomy will need to be iterative (i.e., starting with the initial taxonomy noted above, and refining it as better data become available). After it is developed, the Advisory Panel will also be asked to review and comment on the classification taxonomy that SSA develops initially.

The Advisory Panel will be asked to offer its recommendations regarding the factors that SSA should consider selecting when conducting the statistical analysis that will be used to group DOT-level occupations to form the entities in the initial OIS taxonomic system. For example, if the Advisory Panel concurs that SSA should begin the development process by selecting DOT elements that are the most critical for disability evaluation purposes, the Advisory Panel could offer its input regarding ways to prioritize those elements in terms of their relevance.

If possible, the Advisory Panel can also suggest which DOT elements might be reasonable proxies for psychosocial, behavioral, and cognitive aspects of work. Likewise, if additional non-DOT based descriptors of the DOT occupations exist that the Advisory Panel considers relevant, they could also offer suggestions toward that end.

Developing the Final/Revised Classification System

Forming optimal clusters. After the initial title taxonomy noted above is formed, and the initial round of data-collection and database population for the new OIS is underway using the new job-side data collection processes, SSA will have enough data to begin the

process of analytically determining a revised classification system that is optimal with respect to the taxonomic criteria noted above. As was stressed earlier, ensuring the comprehensiveness of the taxonomy while maintaining adequate levels of homogeneity with respect to work activity and worker requirements are paramount in this regard.

Techniques like the ones used to form the initial taxonomy will again be used in this phase. However, given that we will at that point have access to more detailed and defensible profiles of ratings on each occupation (i.e., based on the use of our new job-side data collection instrument), we should be able to produce a taxonomic system that is far closer to the ideals described above than will be possible in the initial system.

Linking to the SOC. In view of the mandate to be SOC-compliant, SSA will develop appropriate means for linking the taxonomic elements that we rate in our new OIS back to the more abstract occupational clusters defined by the SOC.

Presumably this will take the form of a standard type of crosswalk in which each SSA occupational title is slotted into one of the SOC classifications. However, SSA should also investigate the desirability of using other methods (e.g., ones based on “fuzzy” clustering methods that focus on *probabilities* of membership of each SSA title in a given SOC) to optimize our ability to provide a meaningful interface back to the SOC standard.

Role of Advisory Panel. As in all prior steps of the process of developing the new OIS, SSA will consult closely with the Advisory Panel to obtain their input and advice regarding all aspects of the process of finalizing and updating the title taxonomy.

Maintenance Over Time. In light of the constantly changing nature of work, it is clear that the task of developing an occupational taxonomy is one that is never actually finished. In our case, two change-related factors necessitate the use of an ongoing process of updating and maintaining the taxonomy.

First, it is unavoidably the case that work changes over time, due to changes in the economy, technology, demographics, and other factors. These changes require us to continually focus on identifying both emerging new occupations, as well as ones that have effectively become obsolete.

Second, as the OIS database grows in size and coverage over time, such changes may also have implications for the taxonomic structure. That is, the relative of numbers of occupations present in the database representing qualitatively different types of work will exert an impact on the overall taxonomic structure. When combined with the changes in the nature of the work itself that occur over time, it may well be necessary to modify the taxonomic structure over time to ensure that the titles maintain an adequate degree of homogeneity. This can occur both with respect to splitting titles that have grown more homogeneous, as well as combining titles that have grown more similar over time.

Figure 1. The job- and person-side taxonomies of work-related information.

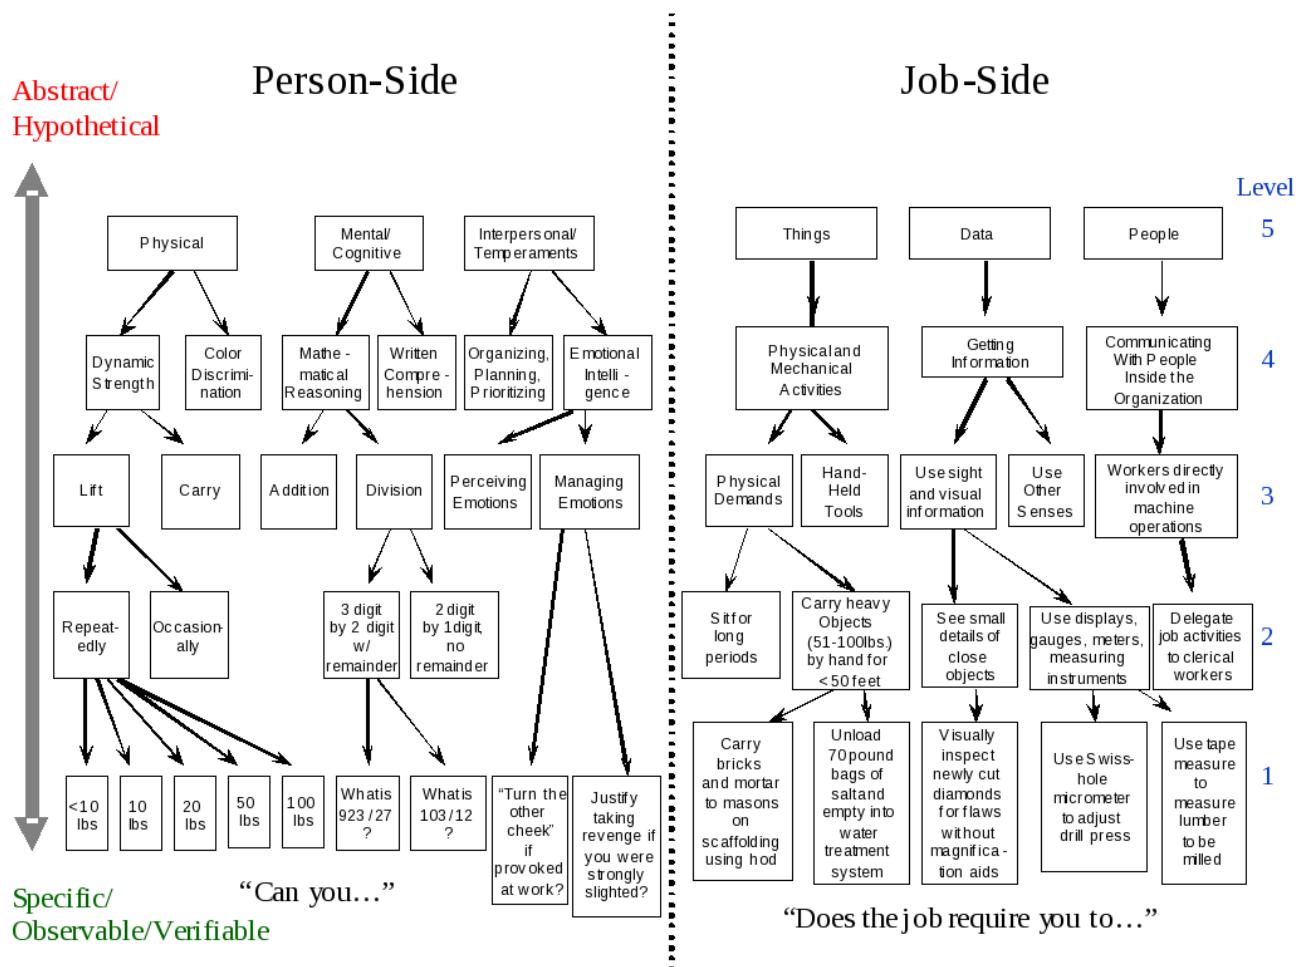

Figure 2. Hierarchy of organizational/occupational entities contained in a title taxonomy.

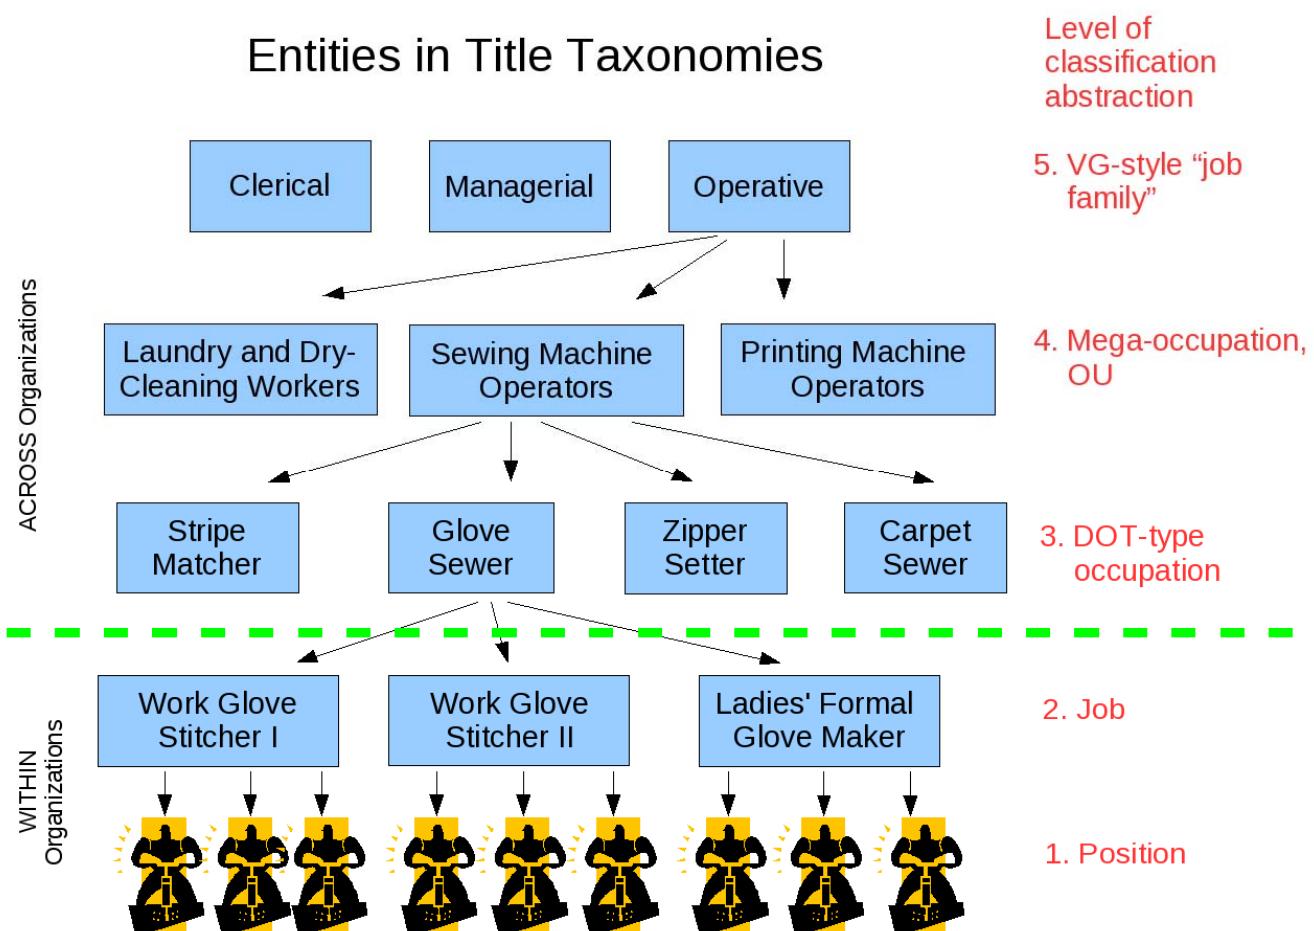

Figure 3. Within-OU variability in the *Carpenters* SOC title on *Strength* and *SVP*.

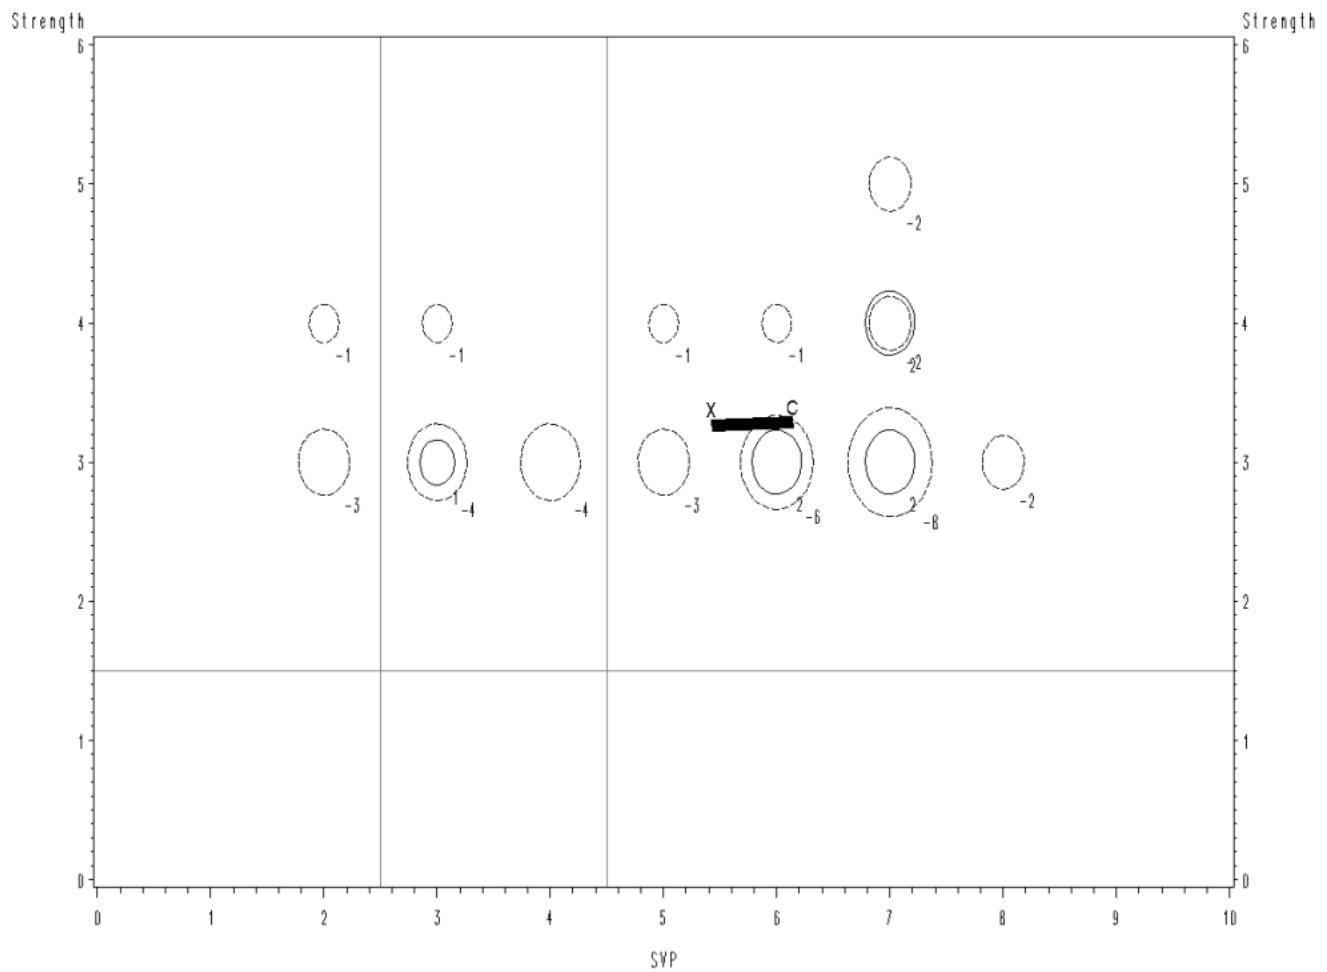

Figure 4. Within-OU variability in *Carpenters* SOC across the 10-factor solution produced by factor analyzing ratings of the occupations on 63 DOT rating scales.

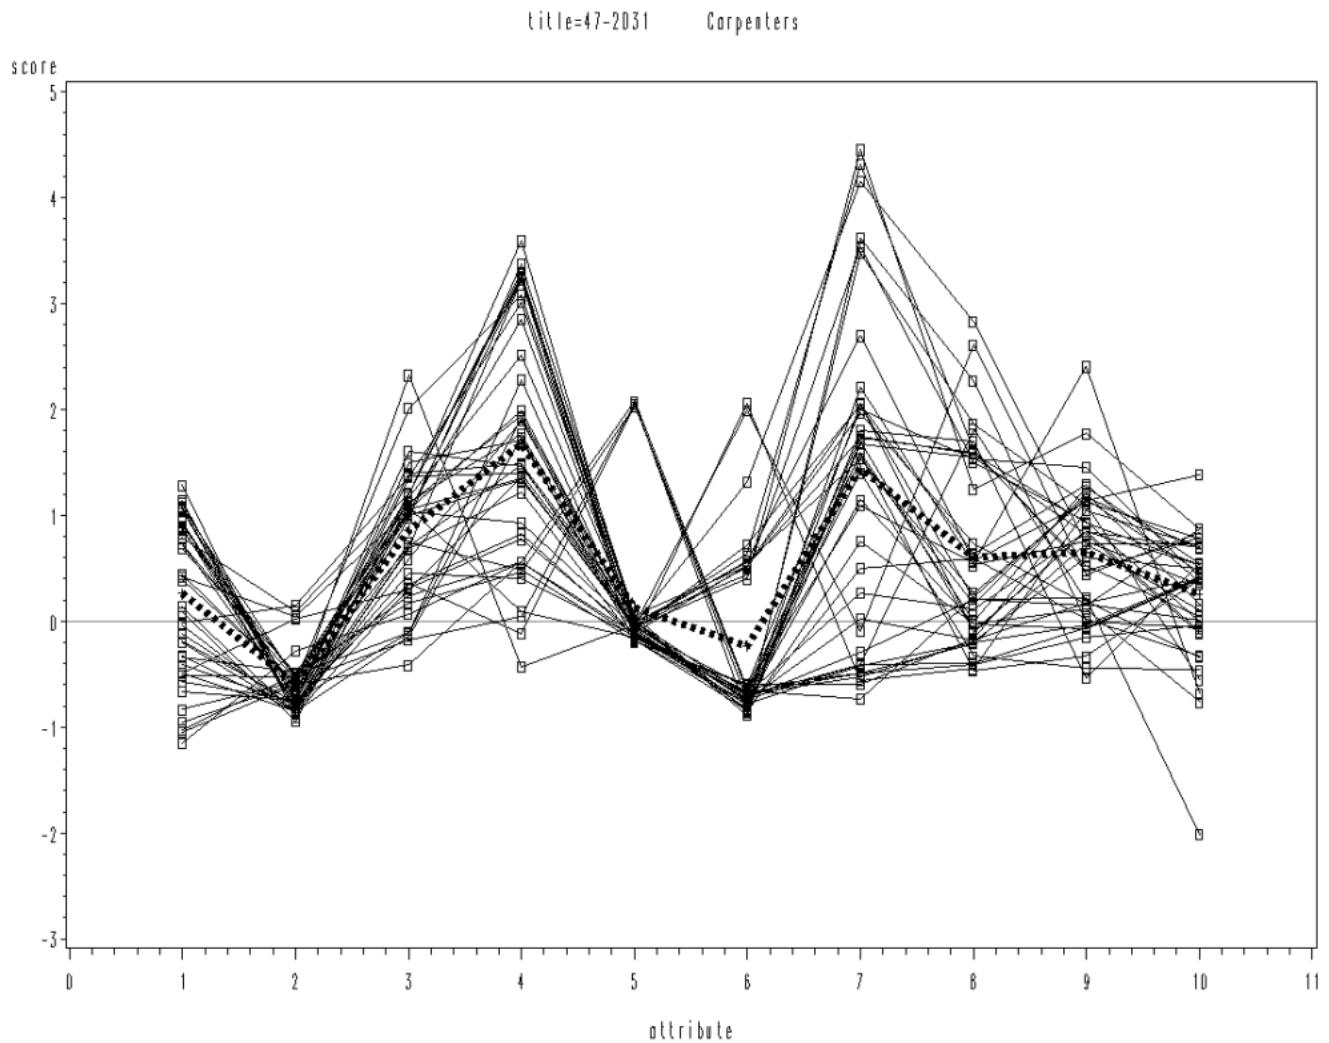

Table 1. Employment by SOC Classification and Within-OU Variability (May 2008).

Note. The 'rank' column shows the rank of the employment in the SOC title as a percentage of total employment; 'emp' = number of employees as of May 2008, 'cumpct' = cumulative percentage of total employment, 'nDOT' = number of DOT titles with DOT trait ratings in the SOC, 'zDist' = standardized average distance of DOT titles in the SOC from the OU-mean profile (higher distances denote more within-OU variability), 'pctMaxDist' = average distance from OU-mean expressed as a percentage of the maximum range of distances seen across all OUs.
